frequencies it was shown for a laminated fiber reinforced periodic cantilever beam that the angle of the plies affects the natural frequencies less as number of plies increase A sensitivity analysis was done investigating the effects of periodic beam parameters on stopbands using the in house MATLAB code and a laminated fiber reinforced composite material Using formulas for effective stiffnesses for symmetric laminated composites a beam element was defined The element was seen to have agreeance with analytical solutions within 2 75% for the first five bending modes Number of plies NP periodic segment ratio PSR periodic ply angle PPA and number of cells NC were swept to show how each affects the location and width of the stopbands Experimental modal testing was conducted to verify the presence of the stop bands utilizing periodic fiber reinforced composite patches An aluminum beam was outfitted with carbon fiber reinforced composite patches and compared to numerical results With the use of an accelerometer shaker and clamp system a cantilever support was created and bending modes of vibration were plotted A trend that resembles the computational results was seen and a stop band was found in a similar frequency range as in the computational results
