

## Inorganic Photochemistry – III

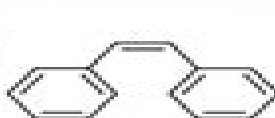

### Photochromism

It is the reversible transformation of a compound between two forms by absorption of electromagnetic radiation, where the two forms have different absorption spectra. Simply it can be described as a reversible change in color on exposure to light. The phenomenon was first observed in 2,3,4,4-tetrachloro naphthalene-1-one in the solid state.

In many cases there is an absorption band in only one form. The degree of change required for a photochemical reaction to be called photochromic is a dramatic change in color. Thus while the cis-trans isomerization of azobenzene is photo chromic that stilbene is not

Trans stilbene

cis stilbene

Since photochromism is just a special case of photochemical reaction almost any photochemical reaction like cis-trans isomerization, pericyclic reaction, intramolecular H transfer, electron transfer etc can be photochromic

A requirement of photochromism is that the two states must be thermally stable. All photochromic molecules isomerize back to their more stable form at some rate and is accelerated by heating.

Many inorganic compounds show photochromism with better fatigue resistance ( i.e loss of sensitivity due to photo oxidation, degradation etc eg AgCl is used in making photochromic lenses. Other silver and Zinc halides are also photochromic.

Photochromic complexes are rare. Two classes are sodium nitroprusside and ruthenium sulfoxide. The mode of action is an excited isomerization of sulfoxide ligand on Ru polypyridine from S to O or O to S leads to a color change and a change in Ru III/II. The ground state is always S bonded and metastable state O bonded.
