3.2.6 Equivalent Energy Density of Electric Power Sources

In order to compare different electric power sources with a battery system it is necessary to transform their parameters into an equivalent mass specific energy E' of the complete system. First, we compare the systems as electric power sources, i.e. the chain up to the electric connector where the motor controller would be plugged in. Figure 8 relates the stored energy to the mass of the electric power source.

The example assumes identical flight performance of a general aviation airplane requiring a propulsive power of 50 kW for fast cruise. The required energy is determined from the respective efficiency chains so that 100 kWh are finally available for the mission. As the airplane has not been adapted to the mass of the propulsion system, this yields an optimistic view for the heavier systems.

The mass given below the fuel tanks are for the fuel and the additional mass of the tank with its fuel systems. It can be seen that a high pressure tank for hydrogen outweighs the fuel mass almost by a factor of 20.

In Figure 9 we can add the motor controller and the electric motor so that the chain extends up to the propeller shaft. This allows comparing the chain with an internal combustion engine.

The results show that the classical internal combustion engine offers the lowest mass and hence an effective specific energy of almost 1600 Wh/kg, which is about 14% of the specific energy content of the raw kerosene fuel. This propulsion system is followed by the hybrid electric system which adds a generator and an electric motor to the drive train.
