**Feature Selection for Knowledge Discovery and Data Mining** Huan Liu, Hiroshi Motoda, 1998-07-31 As computer power grows and data collection technologies advance, a plethora of data is generated in almost every field where computers are used. The computer-generated data should be analyzed by computers; without the aid of computing technologies, it is certain that huge amounts of data collected will not ever be examined, let alone be used to our advantages. Even with today's advanced computer technologies, e.g., machine learning and data mining systems, discovering knowledge from data can still be fiendishly hard due to the characteristics of the computer-generated data. Taking its simplest form, raw data are represented in feature values. The size of a dataset can be measured in two dimensions: number of features  $N$  and number of instances  $P$ . Both  $N$  and  $P$  can be enormously large. This enormity may cause serious problems to many data mining systems. Feature selection is one of the long-existing methods that deal with these problems. Its objective is to select a minimal subset of features according to some reasonable criteria so that the original task can be achieved equally well, if not better. By choosing a minimal subset of features, irrelevant and redundant features are removed according to the criterion. When  $N$  is reduced, the data space shrinks, and in a sense, the data set is now a better representative of the whole data population. If necessary, the reduction of  $N$  can also give rise to the reduction of  $P$  by eliminating duplicates.
